### Background of the Invention

The maintenance of an intact genome is of crucial importance to every organism. The individual cell in a multicellular eukaryotic organism possesses sophisticated and intricate mechanisms to properly respond to DNA damage. Such mechanisms repair damaged DNA or trigger programmed cell death (apoptosis). In response to DNA damage, checkpoint kinases are thought to be intimately involved in these processes. These kinases are activated by upstream proteins, such as ATM (ataxia-telangiectasia mutated) and ATR (ataxia-telangiectasia mutated and rad3-related), and in turn trigger cell cycle arrest by inhibition of proteins such as Cdc25A or Cdc25C. The checkpoint kinases may also modulate the activity of other proteins that are thought to be involved in DNA repair and programmed cell death. Examples of such proteins are BRCA1 and p53.

The checkpoint kinase Cds1 (in man also known as Chk2) is conserved from yeast to man. A human homolog of the *Schizosaccharomyces pombe* Cds1 gene has been described (Tominaga, K. et al. *J. Biol. Chem.* 1999, 274(44):31463–31467; Matsouka, S. et al. *Science* 1998, 282:1893–1897; Blasina, A. et al. *Curr. Biol.* 1999, 9(1):1–10). Human Cds1 was rapidly activated by phosphorylation in response to DNA damage in both normal cells and in p53-deficient cancer cells. High levels of hCds1 were observed in p53-deficient cells. In human cells Cds1 has been implicated in the regulation by phosphorylation of proteins such as p53, BRCA1, Cdc25A, and Cdc25C (See: Lee, J.-S. et al. *Nature* 2000, 404:201–204; Falck, J. et al. *Nature* 2001,

410:842–847; and Buscemi, G. et al. *Mol. Cell. Biol.* 2001, 21(15):5214–5222). As described below, inhibition of Cds1 offers two strategies for improving the effectiveness of DNA-damaging cancer treatments.

Cancer cells are often deficient in the mechanisms responsible for maintaining an intact genome. In particular, they have often lost proper p53 function, which generally correlates with the progression of a tumor to a more aggressive state, such as the progression from a preinvasive to invasive stage of colon cancer, or from a low grade to a high grade astrocytoma. Between 30% and 70% of all subtypes of tumors have a point mutation in one of the two p53 gene copies and have lost the other allele. P53-deficient cells are generally more resistant to radiation. It is thought that the lack of initiation of programmed cell death in cancer cells may render such cells less sensitive to DNA-damaging cancer treatments. The transcription factor p53 is of importance not only for the initiation of programmed cell death, but also in cell cycle arrest. Loss of p53 function may therefore leave cancer cells with limited protection against insult to the genome. Further disruption of DNA damage repair and cell cycle arrest by inhibition of kinases such as Cds1 could then render cancer cells unable to survive after DNA damage. Therefore inhibition of Cds1 could, by removing the remaining components of DNA damage repair, render the cancer cells more susceptible to treatments such as chemical DNA-damaging agents or ionizing radiation.

Normal cells, on the other hand, have an intact p53 system, and will often undergo apoptosis in response to DNA-damaging treatments at a much lower dose than that required to kill cancer cells. Therefore, in such situations, normal cells will be at a disadvantage compared to cancer cells, and cancer treatments often have to be discontinued due to serious side effects caused by loss of normal cells before the cancer has been eradicated. Inhibition of Cds1, which would prevent this kinase from phosphorylating and thereby stabilizing p53, could therefore protect normal cells from the effects of ionizing radiation or DNA-damaging chemotherapeutics while still allowing these agents to be effective against p53-deficient cancer cells. This would have the effect of increasing the therapeutic potential of these agents. This view is supported by studies of mice deficient in Cds1 (See: Hirao, A. et al. *Mol. Cell. Biol.* 2002,

22(18):6521–6532; Takai, H. et al. EMBO J. 2002, 21(19):5195–5205; WO 01/98465 A1 Chugai Seiyaku Kabushiki Kaisha, December 27, 2001). These animals showed increased resistance to the apoptosis caused by ionizing radiation over their wild-type counterparts. For example, it was shown that  
5 these animals were protected from apoptosis of intestinal cells, hair follicle cells, cells of the CNS, and thymus cells relative to their wild-type counterparts when treated with ionizing radiation. Cds1 knockout animals also showed increased survival when exposed to ionizing radiation. It is therefore logical to assume that chemical inhibitors of Cds1 would have therapeutic potential in the  
10 protection of patients from the deleterious side effects of radiation or DNA-damaging chemotherapeutics.

Additional examples of cell cycle checkpoint modulators in development include UCN-01 (CAS 112953-11-4), UCN-02, KW-2401, NSC-638850 (Kyowa Hakko/National Cancer Institute) and SB-218078 (CAS 135897-06-2)

In one aspect, the invention provides a method for treating a subject suffering from cancer, said method comprising administering to said subject a therapeutically effective amount of a pharmaceutical composition comprising a compound of formula (I). According to one aspect, the cancer is p-53 deficient.

In another aspect, the invention provides a method for treating a subject suffering from a p53-deficient tumor, said method comprising (a) administering to said subject a therapeutically effective amount of a pharmaceutical composition comprising a compound of formula (I) and (b) damaging the DNA

of said subject, for example, by administration of a DNA-damaging treatment or agent, such as ionizing radiation or a chemical agent that causes DNA damage. In one aspect, the DNA damaging treatment is provided such that administration of the compound of formula (I) provides effective serum levels of the compound of formula (I) during the treatment and 12 hours to 5 days thereafter, for example, 1-2 days thereafter. In a further aspect, the method of treatment further includes administration of one or more additional anti-cancer agents, to provide in total three or four (or more) agents, to be administered in an effective anti-cancer amount. Multiple or combination therapies may allow use of lower amounts of one or more of the individual agents, when compared with monotherapy, and thereby reducing the incidence or degree of adverse effects.

Examples of such DNA-damaging chemical agents are compounds that cause DNA strand breaks directly such as bleomycin. DNA damage may also be caused by alkylating agents such as hexamethylamine, busulfan, carboplatin, carmustine, cisplatin, cyclophosphamide, dacarbazine, ifosfamide, lomustine, mechlorethamine, melphalan, procarbazine, streptozocin or thiotepa, or combinations thereof. DNA damage may also be caused indirectly by topoisomerase inhibitors such as etoposide, irinotecan, teniposide, topotecan, and doxorubicin or by antimetabolites such as cladribine, cytarabine, floxuridine, 5-fluorouracil, gemcitabine, hydroxyurea, mercaptopurine, methotrexate, pentostatin, thioguanine, and triamterene. Enhancement of DNA damaging effects and improved therapeutic responses can be obtained by combining anticancer agents such as those exemplified above.

A third aspect of the invention provides the use, or the use for the manufacture of a medicament, of a disclosed compound for treating a tumor, in particular, a p53 deficient tumor, and more in particular, a tumor selected from lung, prostate, colon, brain, head and neck, and breast. Other tumors include tumors of the stomach, liver, and ovary. A p-53 deficient tumor is a tumor wherein the functions mediated by p53 are lacking or suppressed due to genetic mutations in the gene encoding p53 or through deficiencies or dysregulation of proteins that modulate p53 expression levels and function.

Examples of such proteins are MDM2 and p14(ARF). A further aspect of the invention includes the treatment of a late-stage, e.g., stage 3 or stage 4, tumor.

The invention also features anti-cancer pharmaceutical compositions comprising as active ingredient an effective amount of a disclosed compound of formula (I), and a pharmaceutically acceptable carrier. The active ingredient can be formulated in any manner suitable for the particular tumor, including aerosol, oral, injectable and topical formulations, and time-release formulations thereof.

Additional features and advantages of the invention will become apparent from the detailed description and examples below, and the appended claims.

the molecule through a carbon atom, such as 3-furyl or 2-imidazolyl, or through a heteroatom, such as N-piperidyl or 1-pyrazolyl. Preferably a monocyclic heterocyclyl has between 4 and 7 ring atoms, or between 5 and 6 ring atoms; there may be between 1 and 5 heteroatoms or heteroatom moieties in the ring, and preferably between 1 and 3. Heterocyclyl also includes fused, e.g., bicyclic, rings, such as those optionally condensed with an optionally substituted carbocyclic or heterocyclic five- or six-membered aromatic ring. For example, "heteroaryl" includes an optionally substituted six-membered heteroaromatic ring containing 1, 2 or 3 nitrogen atoms condensed with an optionally substituted five- or six-membered carbocyclic or heterocyclic aromatic ring. Said heterocyclic five- or six-membered aromatic ring condensed with the said five- or six-membered aromatic ring may contain 1, 2 or 3 nitrogen atoms where it is a six-membered ring, or 1, 2 or 3 heteroatoms selected from oxygen, nitrogen and sulfur where it is a five-membered ring.

5        "Alkanediyl" or "alkylene" represents straight or branched chain optionally substituted bivalent alkane radicals such as, for example, methylene, ethylene, propylene, butylene, pentylene or hexylene.

10        "Alkenediyl" represents, analogous to the above, straight or branched chain optionally substituted bivalent alkene radicals such as, for example, propenylene, butenylene, pentenylene or hexenylene. In such radicals, the carbon atom linking a nitrogen preferably should not be unsaturated.

15        "Aroyl" refers to a carbonyl moiety attached to an optionally substituted aryl or heteroaryl group, wherein aryl and heteroaryl have the definitions provided above. In particular, benzoyl is phenylcarbonyl.

20        As defined herein, two radicals, together with the atom(s) to which they are attached may form an optionally substituted 4- to 7-, 5 – to 7-, or a 5- to 6-membered ring carbocyclic or heterocyclic ring, which ring may be saturated, unsaturated or aromatic. Said rings may be as defined above in the Summary of the Invention section. Particular examples of such rings are as follows in the next section.

25        "Pharmaceutically acceptable salts, esters, and amides" include carboxylate salts (e.g., C<sub>1-8</sub> alkyl, C<sub>3-8</sub> cycloalkyl, aryl, C<sub>2-10</sub> heteroaryl, or C<sub>2-10</sub> non-aromatic heterocyclic) amino acid addition salts, esters, and amides that are within a reasonable benefit/risk ratio, pharmacologically effective and suitable for contact with the tissues of patients without undue toxicity, irritation, or allergic response. "Composition" includes a product comprising the specified ingredients in the specified amounts as well as any product that results directly or indirectly from combinations of the specified ingredients in the specified amounts.

"Therapeutically effective amount" or "effective amount" means that amount of active compound or pharmaceutical agent that elicits the biological or medicinal response in a tissue system, animal or human that is being sought by a researcher, veterinarian, medical doctor or other clinician, which includes alleviation of the symptoms of the condition or disorder being treated.

Concerning the various radicals in this disclosure and in the claims, three general remarks are made. The first remark concerns valency. As with all hydrocarbon radicals, whether saturated, unsaturated or aromatic, and

whether or not cyclic, straight chain, or branched, and also similarly with all heterocyclic radicals, each radical includes substituted radicals of that type and monovalent, bivalent, and multivalent radicals as indicated by the context of the claims. The context will indicate that the substituent is an alkylene or  
5 hydrocarbon radical with at least two hydrogen atoms removed (bivalent) or more hydrogen atoms removed (multivalent). An example of a bivalent radical linking two parts of the molecule is Z in formula (I), which links X and Ar<sub>1</sub>.

Second, radicals or structure fragments as defined herein are

10 understood to include substituted radicals or structure fragments. Hydrocarbyls include monovalent radicals containing carbon and hydrogen such as alkyl, alkenyl, alkynyl, cycloalkyl, and cycloalkenyl (whether aromatic or unsaturated), as well as corresponding divalent radicals such as alkylene, alkenylene, phenylene, and so on. Heterocarbyls include monovalent and divalent radicals  
15 containing carbon, hydrogen, and at least one heteroatom. Examples of monovalent heterocarbyls include acyl, acyloxy, alkoxyacyl, heterocyclyl, heteroaryl, aroyl, benzoyl, dialkylamino, hydroxyalkyl, and so on. Using "alkyl" as an example, "alkyl" should be understood to include substituted alkyl having one or more substitutions, such as between 1 and 5, 1 and 3, or 2 and 4  
20 substituents. The substituents may be the same (dihydroxy, dimethyl), similar (chlorofluoro), or different (chlorobenzyl- or aminomethyl-substituted). Examples of substituted alkyl include haloalkyl (such as fluoromethyl, chloromethyl, difluoromethyl, perchloromethyl, 2-bromoethyl, perfluoromethyl, and 3-iodocyclopentyl), hydroxyalkyl (such as hydroxymethyl, hydroxyethyl, 2-  
25 hydroxypropyl, aminoalkyl (such as aminomethyl, 2-aminoethyl, 3-aminopropyl, and 2-aminopropyl), nitroalkyl, alkylalkyl, and so on. A di(C<sub>1-6</sub> alkyl)amino group includes independently selected alkyl groups, to form, for example, methylpropylamino and isopropylmethylamino, in addition dialkylamino groups having two of the same alkyl group such as dimethyl amino or diethylamino.

30 Third, only stable compounds are intended. For example, where there is an NR'R" group, and R can be an alkenyl group, the double bond is at least one carbon removed from the nitrogen to avoid enamine formation. Similarly,

where a dashed line is an optional  $sp^2$  bond, if it is absent, the appropriate hydrogen atom(s) is(are) included.

Compounds of the invention are further described in the next section.

### C. Synthetic Methods

The invention provides methods of making the disclosed compounds according to traditional organic synthetic methods as well as matrix or combinatorial synthetic methods. Schemes 1 through 12 describe suggested synthetic routes. Using these Schemes, the guidelines below, and the  
5 examples, a person of skill in the art may develop analogous or similar methods for a given compound that are within the invention.

One skilled in the art will recognize that synthesis of the compounds of the present invention may be effected by purchasing an intermediate or protected intermediate compounds described in any of the schemes disclosed  
10 herein. One skilled in the art will further recognize that during any of the processes for preparation of the compounds in the present invention, it may be necessary and/or desirable to protect sensitive or reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in "Protective Groups in Organic  
15 Synthesis", John Wiley & Sons, 1991. These protecting groups may be removed at a convenient stage using methods known from the art.

Examples of the described synthetic routes include Synthetic Examples 1 through 100. Compounds analogous to the target compounds of these examples can be, and in many cases, have been, made according to similar  
20 routes. The disclosed compounds are useful in basic research and as pharmaceutical agents as described in the next section.

Generally, a compound of structure (VII) was synthesized using the methods outlined in Schemes 1 and 2. An aryl or heteroaryl nucleophile of formula (I) in Scheme 1 was added to an aryl or heteroaryl fluoroaldehyde of  
25 formula (II) in the presence of a base, preferably  $\text{Cs}_2\text{CO}_3$ , to form compounds of general formula (III). These aldehydes can then be condensed with a 3,4-diamino-benzamide (VI), in the presence of an oxidizing agent such as  $\text{Na}_2\text{S}_2\text{O}_5$  to provide benzimidazoles (VII). Additionally, compound (VI) can be obtained by condensation of the carboxylate (IV) with ammonia in the presence  
30 of an activating agent such as thionyl chloride. The resulting amide (V) can then be reduced using such reagents as  $\text{SnCl}_2$ , or  $\text{H}_2$  and palladium to afford the diamine of formula (VI).

Scheme 1

Alternatively compounds of formula (VII) can be obtained by the initial  
 5 condensation of an aldehyde of formula (III) with 3,4-diamino-benzoic acid  
 (VIII) (Scheme 2), in the presence of an oxidizing agent such as  $\text{Na}_2\text{S}_2\text{O}_5$  to  
 give a benzimidazole of formula (IX). The carboxylate of (IX) can then be  
 converted to an amide by activation with 1,1'-carbonyldiimidazole (CDI), or  
 other similar activating agent, followed by a nucleophilic amine to provide  
 10 compounds of formula (VII).

Scheme 2

In addition compounds of formula (XI) (Scheme 3) can be obtained by the direct condensation of any commercial or synthesized aryl or heteroaryl aldehyde of formula (III) with a commercial or synthesized phenylenediamine or pyridinediamine of formula (X), in the presence of an oxidizing agent such as  $\text{Na}_2\text{S}_2\text{O}_5$ .

Scheme 3

Compounds of general formula (XIV) can be synthesized by the methods outlined in Scheme 4. A sulfonyl chloride, or acid chloride of formula (XII) can be coupled with an aryl or heteroaryl amine, in the presence of base such as pyridine, to provide an aldehyde of formula (XIII). Alternatively a carboxylic acid of formula (XII) can be treated with an activating agent such as isobutyl chloroformate or 1,1'-carbonyldiimidazole and a base, followed by treatment with an aniline or heteroaryl amine to form amides of general formula (XIII). This compound can then be condensed with a phenylenediamine of formula (X) in the presence of an oxidizing agent such as  $\text{Na}_2\text{S}_2\text{O}_5$  to provide benzimidazoles of formula (XIV).

Scheme 4

Compounds of the general formula (XIX) can be prepared according to the procedures outlined in Scheme 5. A substituted amino-benzoic acid of formula (XV) can be sequentially protected and nitrated by known methods to obtain compounds of formula (XVI). The carboxylate of (XVI) can then be converted to the amide through known coupling procedures, and subsequently deprotected to form compounds of formula (XVII). Reduction of the nitro group using reagents such as NaSH or  $\text{SnCl}_2$  then provides the requisite phenylenediamine of formula (XVIII). Compound (XVIII) can then be condensed with compounds of formula (III), obtained by a method described above, in the presence of an oxidizing agent such as  $\text{Na}_2\text{S}_2\text{O}_5$  to provide compounds of formula (XIX).

Scheme 5

Compounds of general formula (XXI) and (XXIII) can be obtained using the general routes outlined in Scheme 6. Compounds of formula (VIIa), obtained using previously described methods, can be oxidized selectively to either sulfoxides of formula (XXII) or sulfones of formula (XX), using  $TeO_2$  or oxone respectively. Additionally these carboxylates can be converted to amides by treatment with coupling agents such as 1,1'-carbonyldiimidazole, followed by an ammonia source such as  $(NH_4)_2CO_3$  to afford compounds of formula (XXI) or (XXIII).

Scheme 6

Compounds of formula (XXX) can be obtained using the general

- 5 procedures outlined in Scheme 7. Nitro-arylaldehydes or nitro-heteroarylaldehydes of formula (XXVII) can be reduced using  $\text{SnCl}_2$  or other such reducing agent to amines of general formula (XXVIII). The resulting amines can then be treated with an aryl sulfonyl chloride in the presence of base to afford compounds of formula (XXIX). Condensation of (XXIX) with
- 10 phenylenediamines of formula (X) in the presence of an oxidizing agent such as  $\text{Na}_2\text{S}_2\text{O}_5$  provides benzimidazoles of general formula (XXX).

Scheme 7

- Compounds of general formula (XXXVI) can be synthesized using the methods outlined in Scheme 8. Treatment of pyridine (XXXI) with an ammonium equivalent such as  $(\text{NH}_4)_2\text{CO}_3$  provides 2-aminopyridine (XXXII). Removal of the methyl group in (XXXII) with hydrobromic acid and acetic acid, followed by conversion to the bromide using a nucleophilic bromide source such as  $(\text{C}_4\text{H}_9)_4\text{N}^+\text{Br}^-$ , in the presence of  $\text{P}_2\text{O}_5$ , gives compound (XXXIII).
- Treatment of the bromide with a metallic cyanide such as  $\text{CuCN}$  then results in the formation of compound (XXXIV). Reduction of the nitro group of (XXXIV) using  $\text{H}_2$  and  $\text{Pd}$  or other reducing agent, followed by condensation with an aryl aldehyde of type (III) in the presence of an oxidizing agent such as  $\text{Na}_2\text{S}_2\text{O}_5$  provides imidazopyridines of general formula (XXXV). The cyano group of (XXXV) can then be converted to an amide of formula (XXXVI) by hydrolysis with  $\text{BF}_3$  in acetic acid.

Scheme 8

Compounds of general formula (XXVI) were synthesized by the general methods described in Scheme 9. A fluoro-arylaldehyde or halo-heteroarylaldehyde of general formula (II) can be treated with a piperazine of formula (XXIV) in the presence of a base such as  $\text{Cs}_2\text{CO}_3$  to afford compounds of general formula (XXV). Condensation of (XXV) with phenylenediamines of formula (X) in the presence of an oxidizing agent such as  $\text{Na}_2\text{S}_2\text{O}_5$  provides benzimidazoles of general formula (XXVI).

Scheme 9

Compounds of general formula (VIIc) can be synthesized from compounds of formula (VIIb) by the methods described in Scheme 10.

- 5 Compounds of general formula (VIIb), obtained from the methods described in Scheme 1, are treated with a coupling agent such as 1,1'-carbonyldiimidazole, or other similar coupling agent, and a nucleophilic amine to provide amides of formula (VIIc).

10 Scheme 10

- 15 Compounds of general formula (VIIf) can be synthesized by the methods outlined in Scheme 11. Compounds of formula (VIId), obtained using previously described methods, can be reduced using H<sub>2</sub> and Pd or other reducing agent. The resulting amines of formula (VIIe) can be treated with a sulfonyl chloride (X = SO<sub>2</sub>) or acid chloride (X = CO), under basic conditions to provide benzimidazoles of general formula (VIIf).

Scheme 11

Compounds of general formula (VIIh) can be synthesized using the route outlined in Scheme 12. Compounds of formula (VIIg), obtained using previously described methods, can be treated with boron tribromide to remove the methyl group and provide benzimidazoles of general formula (VIIh).

#### D. Formulation and Administration

The present compounds inhibit the checkpoint modulator Cds1 and therefore are useful as a medicine especially in methods for treating patients suffering from disorders or conditions that are modulated or regulated by Cds1, such as cancer.

The invention features a method for treating a subject with cancer, said method comprising administering to the subject a therapeutically effective amount of a pharmaceutical composition comprising a compound of the invention. The invention also provides a method for inhibiting Cds1 activity in a subject, wherein the method comprises administering to the subject a therapeutically effective amount of a pharmaceutical composition comprising a compound of the invention.

The compounds of the present invention may be formulated into various pharmaceutical forms for administration purposes. To prepare these pharmaceutical compositions, an effective amount of a particular compound, in base or acid addition salt form, as the active ingredient is intimately mixed with a pharmaceutically acceptable carrier.

A carrier may take a wide variety of forms depending on the form of preparation desired for administration. These pharmaceutical compositions are desirably in unitary dosage form suitable, preferably, for oral administration, intravenous injection or parenteral injection. For example, in preparing the compositions in oral dosage form, any of the usual pharmaceutical media may be employed. These include water, glycols, oils, alcohols and the like in the case of oral liquid preparations such as suspensions, syrups, elixirs and solutions; or solid carriers such as starches, sugars, kaolin, lubricants, binders, disintegrating agents and the like in the case of powders, pills, capsules and tablets. In view of their ease in administration, tablets and capsules represent the most advantageous oral dosage unit form, in which case solid pharmaceutical carriers are generally employed. For parenteral compositions, the carrier will usually comprise sterile water, at least in large part, though other ingredients, for example, to aid solubility, may be included. Injectable solutions, for example, may be prepared in which the carrier comprises saline solution, glucose solution or a mixture of saline and glucose solution. Injectable suspensions may also be prepared in which case appropriate liquid carriers, suspending agents and the like may be employed. In the compositions suitable for percutaneous administration, the

carrier optionally comprises a penetration enhancing agent and/or a suitable wetting agent, optionally combined with suitable additives of any nature in minor proportions, which additives do not cause a significant deleterious effect to the skin. Such additives may facilitate the administration to the skin and/or may be helpful for preparing the desired compositions. These compositions may be administered in various ways, e.g., as a transdermal patch, as a spot-on, as an ointment. Acid addition salts of the compounds of formula I, due to their increased water solubility over the corresponding base form, are more suitable in the preparation of aqueous compositions.

It is especially advantageous to formulate the aforementioned pharmaceutical compositions in dosage unit form for ease of administration and uniformity of dosage. Dosage unit form as used in the specification herein refers to physically discrete units suitable as unitary dosages, each unit containing a predetermined quantity of active ingredient calculated to produce the desired therapeutic effect in association with the required pharmaceutical carrier. Examples of such dosage unit forms are tablets (including scored or coated tablets), capsules, pills, powder packets, wafers, injectable solutions or suspensions, teaspoonfuls, tablespoonfuls and the like, and segregated multiples thereof.

Pharmaceutically acceptable acid addition salts include the therapeutically active non-toxic acid addition salt forms that the disclosed compounds are able to form. The latter can conveniently be obtained by treating the base form with an appropriate acid. Appropriate acids comprise, for example, inorganic acids such as hydrohalic acids, e.g. hydrochloric or hydrobromic acid; sulfuric; nitric; phosphoric and the like acids; or organic acids such as, for example, acetic, propanoic, hydroxyacetic, lactic, pyruvic, oxalic, malonic, succinic, maleic, fumaric, malic, tartaric, citric, methanesulfonic, ethanesulfonic, benzenesulfonic, *p*-toluenesulfonic, cyclamic, salicylic, *p*-aminosalicylic, palmoic and the like acids. The term addition salt also comprises the solvates that the disclosed compounds, as well as the salts thereof, are able to form. Such solvates are for example hydrates, alcoholates

and the like. Conversely the salt form can be converted by treatment with alkali into the free base form.

Stereoisomeric forms defines all the possible isomeric forms that the compounds of formula (I) may possess. Unless otherwise mentioned or indicated, the chemical designation of compounds denotes the mixture of all possible stereochemically isomeric forms, said mixtures containing all diastereomers and enantiomers of the basic molecular structure. More in particular, stereogenic centers may have the (R)- or (S)-configuration; substituents on bivalent cyclic saturated radicals may have either the cis- or trans-configuration. The invention encompasses stereochemically isomeric forms including diastereoisomers, as well as mixtures thereof in any proportion of the disclosed compounds. The disclosed compounds may also exist in their tautomeric forms. Such forms although not explicitly indicated in the above and following formulae are intended to be included within the scope of the present invention. For example, the present invention includes

2-[4-(4-Chloro-phenoxy)-phenyl]-1*H*-benzimidazole-5-carboxylic acid amide as well as

2-[4-(4-Chloro-phenoxy)-phenyl]-3*H*-benzimidazole-5-carboxylic acid amide.

Those of skill in the treatment of disorders or conditions mediated by the Cds1 enzyme could easily determine the effective daily amount from the test results presented hereinafter and other information. In general it is contemplated that a therapeutically effective dose would be from 0.001 mg/kg to 100 mg/kg body weight, more preferably from 1 mg/kg to 50 mg/kg body weight. It may be appropriate to administer the therapeutically effective dose

as two, three, four or more sub-doses at appropriate intervals throughout the day. Said sub-doses may be formulated as unit dosage forms, for example, containing 1 mg to 2000 mg, and in particular 10 to 500 mg of active ingredient per unit dosage form. Examples include 10 mg, 25 mg, 50 mg, 100 mg, 150 mg, 250 mg, and 500 mg dosage forms. Compounds of the invention may also be prepared in time-release or subcutaneous or transdermal patch formulations. Disclosed compound may also be formulated as a spray or other topical or inhalable formulations.

The exact dosage and frequency of administration depends on the particular compound of formula (I) used, the particular condition being treated, the severity of the condition being treated, the age, weight and general physical condition of the particular patient as well as other medication the patient may be taking, as is well known to those skilled in the art. Furthermore, it is evident that said effective daily amount may be lowered or increased depending on the response of the treated patient and/or depending on the evaluation of the physician prescribing the compounds of the instant invention. The effective daily amount ranges mentioned herein are therefore only guidelines.

The next section includes detailed information relating to the use of the disclosed compounds.

Adenosine Triphosphate. The agarose beads were washed repeatedly with a 0.1% solution of Tween-20 in Phosphate-buffered saline, pH 7.4. Enzyme activity at different Cds1 inhibitory compound concentrations was determined by measuring the amount of radioactive phosphate bound to the substrate peptide by scintillation counting. Results are expressed as IC<sub>50</sub> in Table 1 below.

Example 102Determination of the effect of Cds1 inhibitory compounds on tumor cell line clonogenic survival

5           Typically 3 to 300 cells from an established tumor line were plated per  $\text{cm}^2$  in petri dishes in the appropriate growth medium at 37 °C. Cells were exposed to compounds dissolved in the growth medium from appropriately formulated stock solutions for times ranging from 12 to 48 h. During the course of compound exposure the cells were treated with a second agent with DNA-  
10   damaging capabilities, such as ionizing radiation or certain chemotherapeutic compounds. After this treatment regimen cells were incubated in growth medium containing no compound for a period of 7 to 14 days. At that time the cells were fixed with methanol and stained with 0.25% crystal violet. The number of colonies of cells exceeding 50 cells was determined for each  
15   treatment, and this number was used to calculate the effect of compounds on the survival of cells. When cells were exposed to compound 1, a decrease in the number of colonies of cells was observed as compared to a control group having no compound 1.

20   Example 103Effect of Cds1 inhibitors on tumor growth in murine xenograft models

One  $\times 10^6$  to ten  $\times 10^6$  tumor cells from an established tumor cell line are injected in the hind limbs of athymic nu/nu mice. Tumors are allowed to grow  
25   until they reach 30–100  $\text{mm}^3$ . At that time mice are randomized into different treatment groups, and compound or vehicle is administered by injection or oral gavage. The mice are irradiated locally on the tumor using a radiation source such as a  $^{137}\text{Cs}$  irradiator. This treatment regimen is typically repeated one to three times. After this treatment tumor growth rate is followed by measurement  
30   of tumor size twice weekly in three orthogonal directions, which is used to calculate the tumor volume. The results of this procedure using Compound 1 were inconclusive.

## Example 104

Determination of the effect of Cds1 inhibitory compounds on radiation-induced apoptosis in isolated primary cells

Spleen cells were isolated from C57/BL6 mice as follows: Spleens were disrupted by grinding between two frosted glass slides, and cells were passed through a cell strainer. Erythrocytes were lysed by incubation in ammonium chloride solution followed by careful washing of cells in isotonic medium. The spleen cells were plated in 60 mm petri dishes at  $5 \times 10^6$  cells/mL in RPMI medium containing 10% fetal calf serum and Cds1 inhibitor. One hour after plating of cells with compound, the cells were dosed with 0.5-1 Gy from a  $^{137}\text{Cs}$   $\gamma$ -radiation source. Determination of apoptotic cells by Annexin V staining was performed using the Annexin V-FITC Apoptosis Detection Kit™ (Cat# PF032 Oncogene Research Products) according to the manufacturer's instructions. Briefly, 6–24 h after irradiation, the cells were washed with buffered isotonic salt solution and suspended at  $1 \times 10^6$  cells/mL in binding buffer (10 mM Hepes pH 7.4, 150 mM NaCl, 2.5 mM  $\text{CaCl}_2$ , 1 mM  $\text{MgCl}_2$ , 4% bovine serum albumin) containing 80 ng/mL Annexin V labelled with FITC and 0.4  $\mu\text{g/mL}$  anti-B220 antibody labelled with allophycocyanin. The cells were then pelleted and resuspended in binding buffer containing 0.6  $\mu\text{g/mL}$  propidium iodide. The stained cells were analyzed on a FACS machine (Fluorescence Activated Cell Sorter™, Becton Dickinson). The fraction of viable, non-apoptotic cells was determined by quantifying the number of cells that did not stain with propidium iodide or Annexin V versus the total number of cells. Fraction of non-apoptotic B-cells or total cells were determined separately based on staining with the B220 antibody mentioned above. It was found that compounds set forth in Example 1, 9, 11, 38, 42, 43, 84, 87, 88, 94, 97 and 106 (each of the three) protected spleen B cells from radiation-induced apoptosis.

## Example 105

Determination of the effect of Cds1 inhibitory compounds on radiation-induced apoptosis in splenocytes *in vivo*

Female C57/BL mice, 6–8 weeks of age, were dosed by oral gavage or by injection with Cds1 inhibitory compound before and at regular intervals after radiation exposure. One to three hours after first compound dose, the animals were irradiated with  $\gamma$ -rays administered to the whole animal at a dose between 0.5 and 4 Gy. At times between 4 and 24 h after irradiation, the animals were sacrificed, and the tissues of interest were excised. Cell apoptosis was quantified using Annexin V staining as described in Example 104. When animals was dosed with the compound set forth in Example 1 and exposed to 4Gy radiation protection of spleen cells from apoptosis was observed compared to animals dosed with vehicle alone. Apoptosis can be studied in a variety of tissues. In some cases other methods for quantification of apoptosis than the method described in Example 104 may be more appropriate. Thus, apoptosis can also be determined by detection of DNA degradation by TUNEL staining, as described by Darzynkiewicz and Bedner (In *Analysis of Apoptotic Cells by Flow and Laser Scanning Cytometry*; Reed, J.C., Ed.; Methods of Enzymology, Vol. 322; Academic Press: San Diego, 2000; 18–39). Briefly, cells or tissues are fixed with formaldehyde and permeabilized with ethanol, and DNA ends are then labelled by attaching nucleotide derivatives such as BrdUTP using the enzyme terminal deoxynucleotidyl transferase. DNA ends can then be detected by incubating the cells or tissues with fluorescently-labelled antibodies reactive with BrdU. Quantification can be done by laser scanning cytometry, by visual microscopical examination or by FACS.

## Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: —  
because they relate to subject matter not required to be searched by this Authority, namely:  
see FURTHER INFORMATION sheet PCT/ISA/210
2. ☐ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
